

### -:- APV approach :-

- Similar to MM model on Capital Structure with taxes.
- Also, revisited in Business Valuation - new topic - valuation of distress firms.

Eg: 2 firms in the same risk class & EBIT of 400000  
 $t = 30\%$  Business risk &  $\sigma_{EBIT}$  are same

Unlevered firm: Value ( $V_u$ ) = 2500000,  $k_c^* = ?$

Levered firm: Debt = 1000000 @ 10%.

$V_L = ?$

Equity value = ?

$k_c$  &  $k_e = ?$

Soln:-

$$1) V_u = \frac{EBIT(1-t)}{k_c^*}$$

$$k_c^* = \frac{400000(1-0.3)}{2500000} \times 100 = 11.2\%$$

$$2) V_L = V_u + D \times t = 2500000 + (1000000 \times 0.3) = 2800000$$

$$3) \text{Value of Equity (S)} = 2800000 - 1000000 = 1800000$$

$$4) k_c = \frac{NOPAT}{V_L} = \frac{400000 \times 0.7}{2800000} \times 100 = 10\%$$

$$5) k_e = \frac{PAT}{S} = \frac{(400000 - 100000) \times 0.7}{1800000} = 11.67\%$$

### Adjusted Present Value (APV) Approach.

Lets segregate investment aspect & financing aspect

of the project.

### Step 1 : Base Case APV.

= NPV of project as if there is no debt & there are no capital market imperfections like flotation cost.

= PV of unlevered CF disc. @ unlevered  $k_e$ .

(• unlevered  $k_e$  = opportunity cost of capital.  
cost of equity kya hota agar debt aur flotation cost nahi hote....)

Unlevered CF & unlevered  $k_e$  shall be given.

### Step 2 : Flotation Cost → Common sense. 😊

### Step 3 : Tax advantage of Debt (TAD)

= PV of Interest Tax Shield disc. @ ' $r$ '

Assume debt is perpetual

$$\therefore TAD = \frac{r \times t \times D}{r} \quad \frac{A}{i}$$

$$= t \times D$$

Repayment pattern & tenure of debt given

↓  
Apply common sense 😊

#### 1) Step 1 : Base Case NPV

$$= 28.5 \times PVAF(15\%, 7) - 120$$

$$= -1.428 \text{ lakhs}$$

[Self note: iska mtlb project unviable h agar purely equity financed h....]

$$\therefore \text{Base Case NPV} = -1.428 \text{ lakhs}$$

## 2) Step 2: Adjusted NPV

$$\rightarrow \text{Floatation cost} = \frac{60}{0.95} \times 0.05 = 3.16 \text{ lakhs.}$$

$$\rightarrow \text{Tax Advantage of Debt disc. @ 12\%}$$

6% 6 months ka hai toh saal ka effective int. =  $(1.06)^2 - 1 = 12.36\%$

| Yrs                          | Amount<br>₹ | Interest<br>@ 12% | Total<br>Interest | Interest Tax<br>Shield | P.V. @ 12.36% |
|------------------------------|-------------|-------------------|-------------------|------------------------|---------------|
| 1: 1 <sup>st</sup> 1/2       | 60          | 3.6               | 7.2               | 2.16<br>(7.2 × 0.3)    | 1.92          |

| 4: 1 <sup>st</sup> 1/2       | 40          | 2.4               | 4.5               | 1.35<br>(4.5 × 0.3)    | 0.85          |
| 2 <sup>nd</sup> 1/2          | 35          | 2.1               |                   |                        |               |
| 5: 1 <sup>st</sup> 1/2       | 30          | 1.8               | 3.3               | 0.99<br>(3.3 × 0.3)    | 0.55          |
| 2 <sup>nd</sup> 1/2          | 25          | 1.5               |                   |                        |               |
| 6: 1 <sup>st</sup> 1/2       | 20          | 1.2               | 2.1               | 0.63<br>(2.1 × 0.3)    | 0.31          |
| 2 <sup>nd</sup> 1/2          | 15          | 0.9               |                   |                        |               |
| 7: 1 <sup>st</sup> 1/2       | 10          | 0.6               | 0.9               | 0.27<br>(0.9 × 0.3)    | 0.12          |
| 2 <sup>nd</sup> 1/2          | 5           | 0.3               |                   |                        |               |
| Tax Advantage of Debt = 6.60 |             |                   |                   |                        |               |

$$\text{APV} = \text{Base case NPV} - \text{Issue cost} + \text{Tax advantage of debt}$$

$$= -1.428 - 3.16 + 6.6$$

$$\therefore \text{APV} = 2.012 \text{ lakhs}$$

we have calculated ITS assuming we will get it at the end of each year & calculated its PV accordingly

Conclusion: So the project which was not viable with 100% equity financing is now viable given the tax advantage of debt.

Note: We have not considered tax shield on the issue cost. Alternatively, post tax issue cost =  $3.16 \times 0.7 = 2.21$

$$\therefore \text{APV} = -1.428 - 2.21 + 6.6 = 2.962$$

Q.2

Step 1: Base Case NPV

$$= \frac{A - I}{i} = \frac{42}{0.14} = 300 - 270 = 30 \text{ lakhs}$$

Step 2: Issue Cost = 10 lakhs .... (given)

Step 3: Tax Advantage of Debt

$$\text{Debt} = 270 + 10 = 280 \text{ lakh} @ 10\% \text{ \& tax rate} = 30\%$$

$$\begin{aligned} \therefore \text{Tax advantage of debt} &= t \times D \\ &= 0.3 \times 280 \\ &= 84 \text{ lakhs} \end{aligned}$$

$$\begin{aligned} \text{APV} &= \text{Base Case NPV} - \text{Issue cost} + \text{Tax advantage of debt} \\ &= 30 - 10 + 84 \end{aligned}$$

$$\therefore \text{APV} = 104 \text{ lakhs}$$

Q.3

W.N.] Cash Flow

|                       |               |
|-----------------------|---------------|
| Revenue               | 1200000       |
| (-) Op. Exp.          | <u>400000</u> |
| EBDIT                 | 800000        |
| (-) Depr <sup>n</sup> | <u>500000</u> |
| EBIT                  | 300000        |
| NOPAT @ 70%           | 210000        |
| (+) Depr <sup>n</sup> | <u>500000</u> |
| CFAT                  | <u>710000</u> |

$\therefore$  Cash Flow for firm = 710000

\*  $k_c^*$ : Unlevered  $k_e$ .

$$R_e = R_f + (R_m - R_f) \beta \rightarrow \text{CAPM}$$

where,  $\beta$  = systematic risk.

Market Risk.

If market  $\Delta$  by 1%, stk  $\Delta$  by  $\beta\%$ .

$$\beta \begin{cases} \beta_u: \text{only business risk.} \\ \beta_L: \text{Business + Financial risk.} \end{cases}$$

$k_c^*$  = Unlevered  $k_e$

$$= R_f + (R_m - R_f) \beta_u$$

(unlevered  $\beta$ )

$$k_c^* = R_f + (R_m - R_f) \beta_u = 5 + 6 \times 1.5 = 14\% \text{ (unlevered } k_e)$$

$$1) \text{ Base Case NPV} = 710000 \times \text{PVAF}(14\%, 5) - 2500000$$

$$= -62512.5$$

$$2) \text{ Issue cost of NPV} = \frac{40\% \text{ of } 2500000}{98\%} \times 2\% \approx 20408$$

3) Tax Advantage of Debt -

$$\text{Debt} = 60\% \text{ of } 2500000 = 1500000$$

$$\text{Interest rate} = 8\%$$

$$\text{tax rate} = 30\%$$

Assuming that debt is repayable one-shot i.e. lumpsum at the end of 5 years.

$$\text{Annual ITS} = 30\% \text{ of } 8\% \text{ of } 1500000 =$$

$$= 36000 \text{ p.a. for 5 years.}$$

$$\text{Tax advantage of Debt} = \text{PV of ITS @ } 8\%$$

If question states, interest tax shield is certain, then we should use  $R_f = 5\%$  as discount rate for tax advantage of debt.

$$= 36000 \times \text{PVAF}(8\%, 5)$$

$$= 143738$$

$$4) \text{ APV} = \text{Base Case NPV} - \text{Floatation cost} + \text{tax advantage of debt}$$

$$= -62512.5 - 20408 + 143738$$

$$= 60817.5 \therefore \text{Project is viable}$$

If a company has losses  $\rightarrow$  no tax shield.  
To get Tax shield, Co. got to have profits.

Note :-

$$1) \text{ Alternatively, after tax floatation cost}$$

$$= 20408 \times 0.7$$

$$= 14286$$

$$\text{This gives APV} = -62512.5 - 14286 + 143738 = 66939$$

2) Problem remaining silent, we have assumed that loan is repayable lumpsum on maturity.

3) If the firm is definitely going to make positive profits in future, ITS becomes certain & disc. rate for TAD should be  $R_f = 5\%$ .

|              |   |   |   |   |   |       |
|--------------|---|---|---|---|---|-------|
